

# Chunking Strategy for Task Project

Chunking is a technique used in Retrieval Augmented Generation (RAG) and document processing systems to split large documents into smaller, meaningful segments before indexing them in a vector database. Proper chunking improves retrieval accuracy, reduces context loss, and helps language models generate more relevant responses. Common approaches include fixed-size chunking, recursive chunking, semantic chunking, and document-aware chunking. The choice of strategy depends on the structure of the source content, token limits, and the retrieval requirements of the application.

| Strategy       | Description                      | Best Use Case           |
|----------------|----------------------------------|-------------------------|
| Fixed-size     | Split by character/token count   | Simple text documents   |
| Recursive      | Split while preserving structure | Reports and manuals     |
| Semantic       | Split by meaning and context     | Knowledge bases         |
| Document-aware | Split by headings/sections       | Technical documentation |
